Mayil Krishnam, MD
Ramit Lamba, MD
Michael McNitt-Gray, PhD
Anthony Seibert, PhD
Diana L. Miglioretti, PhD

Purpose: To summarize data on computed tomographic (CT) radiation doses collected from consecutive CT examinations performed at 12 facilities that can contribute to the creation of reference levels.

Materials and Methods: The study was approved by the institutional review boards of the collaborating institutions and was compliant with HIPAA. Radiation dose metrics were prospectively and electronically collected from 199 656 consecutive CT examinations in 83 181 adults and 3871 consecutive CT examinations in 2609 children at the five University of California medical centers during 2013. The median volume CT dose index ($CTDI_{vol}$), dose-length product (DLP), and effective dose, along with the interquartile range (IQR), were cal-

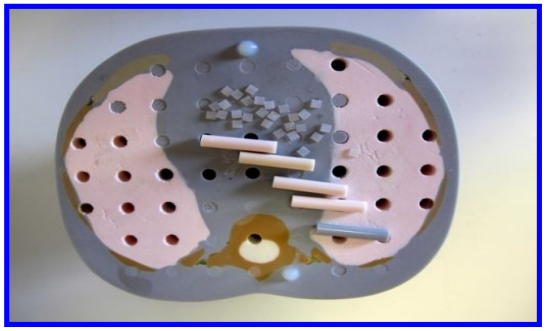
Effective dose ‘hides’ differences in the doses delivered to various organs from CT examinations

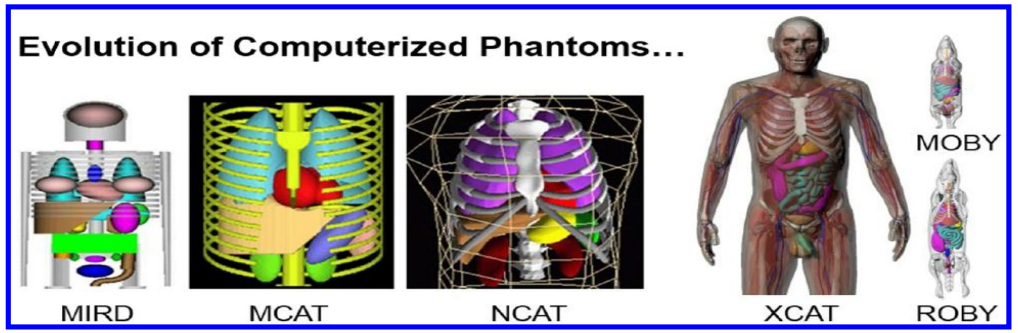
CCTA: Dose with 256-slice scanning

Effective Dose: < 2.0 mSv (Prospective mode)

Breast Dose: 14 mGy
Lung Dose: 9 mGy

It's important to focus on organ doses





Anthropomorphic phantoms represent only

standard size patients of standard ages

There are obvious differences in the anatomy and size of patients. Consequently, there may be considerable differences in the outer dimensions and organ location between phantoms and patients undergoing examinations

Patient-specific and equipment-specific dosimetry is needed

Most existing dose estimation methods don't take into consideration

- dual energy techniques

- parameters influencing dose such as contrast material

- new dose reduction tools (automatic kV selection ,

organ dose modulation etc)

Estimating the Patient-specific Dose to the Thyroid and Breasts and Overall Risk in Chest CT When Using Organ-based Tube Current Modulation[1]

Caro Franck, MSc
Peter Smeets, MD
Lore Lapeire, MD
Eric Achten, MD, PhD
Klaus Bacher, PhD

Purpose: To assess the potential dose reduction to the thyroid and breasts in chest computed tomography (CT) with organ-based tube current modulation (OBTCM).

Materials and Methods: In this retrospective study (from January 2015 to December 2016), the location of the breasts with respect to the reduced tube current zone was determined. With Monte Carlo simulations, patient-specific dose distributions of

Figure 1

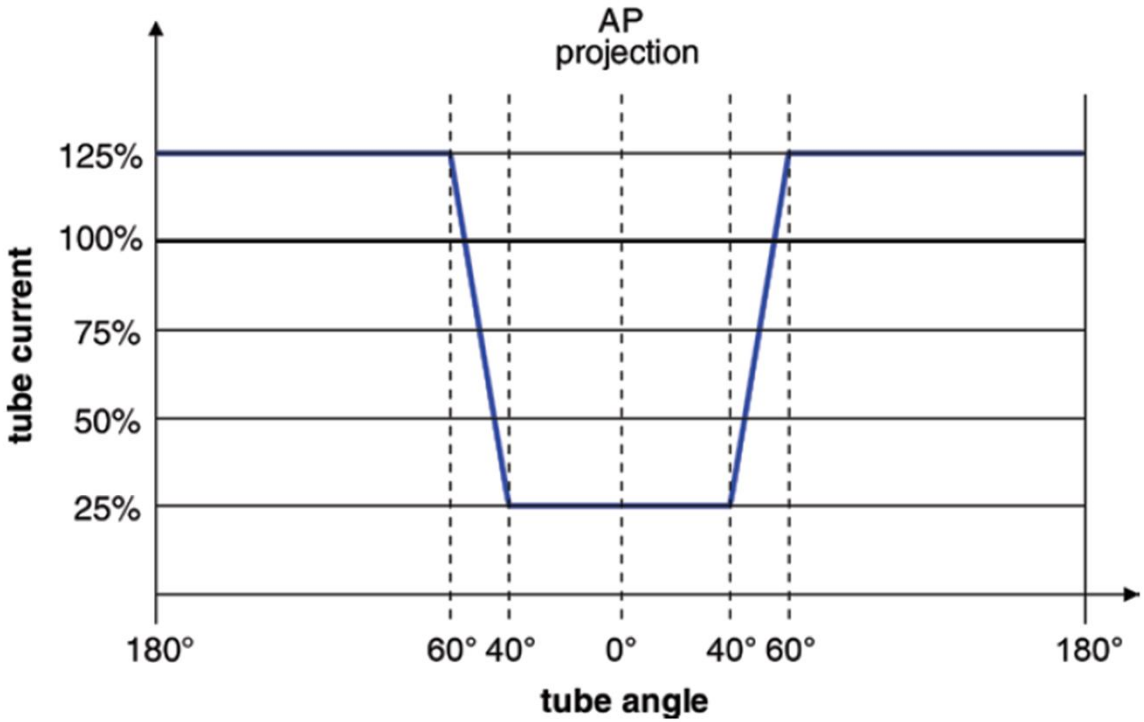

Figure 1: Graph shows that organ-based tube current modulation with X-CARE (Siemens Healthcare, Erlangen, Germany) reduces dose to anteriorly located organs by lowering tube current in axial plane within a range of 80°. To maintain image quality, tube current is higher during lateral and posterior part of body circumference. Relative milliampere values are shown, normalized to average tube current during one rotation. *AP* = anteroposterior. (Data from Siemens Healthcare.)

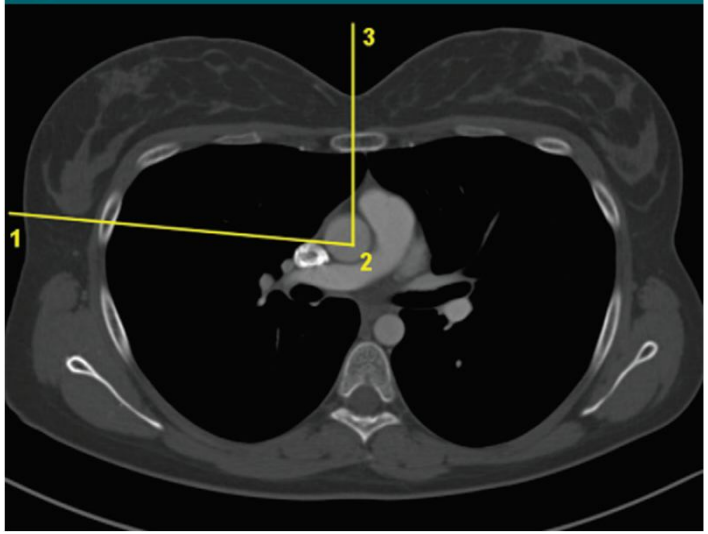
Table 3

Mean Organ Dose and Mean Percentage Dose Reduction

Organ ($n = 17$)	Organ Dose (mGy)			Potential Dose Reduction (%)	*P* Value	Clinical Dose Reduction (%)	*P* Value
	Standard Acquisition	Virtual OBTCM	OBTCM Acquisition				
Thyroid	21 ± 8	15 ± 6	17 ± 7	28 ± 5	<.001	18 ± 32	.04
Breast	17 ± 3	14 ± 3	16 ± 3	18 ± 3	<.001	9 ± 10	.003
Lung	15 ± 3	14 ± 3	17 ± 3	4 ± 2	<.001	−17 ± 19	.005
Liver	15 ± 3	13 ± 1	16 ± 2	10 ± 4	<.001	−11 ± 14	.01
Kidney	13 ± 1	14 ± 1	16 ± 2	−4 ± 3	<.001	−26 ± 18	<.001

Note.—Standard chest scans and organ-based tube current modulation simulations are compared. To compute the potential dose reduction, the same patient voxel models and scanning parameters are used as for the standard scans. The clinical dose reduction is based on the available CT data for 17 patients. Negative values indicate an increase in organ dose. Dose differences are statistically significant. OBTCM = organ-based tube current modulation.

Figure 3



Conclusion: The potential benefit of OBTCM to the female breast in chest CT is overestimated because of a limited reduced tube current zone; despite a 9% dose reduction to the female breast, posterior organs will absorb up to 26% more radiation, resulting in no reduction in radiation-induced malignancies.

Radiology

The Effect of Contrast Material on Radiation Dose at CT:

Part II. A Systematic Evaluation across 58 Patient Models[1]

Pooyan Sahbaee, PhD
Ehsan Abadi, MS
W. Paul Segars, PhD
Daniele Marin, MD
Rendon C. Nelson, MD
Ehsan Samei, PhD

Purpose: To estimate the radiation dose as a result of contrast medium administration in a typical abdominal computed tomographic (CT) examination across a library of contrast material–enhanced computational patient models.

Materials and Methods: In part II of this study, first, the technique described in part I of this study was applied to enhance the extended cardiac-torso models with patient-specific iodine-time profiles reflecting the administration of contrast material. Second, the patient models were deployed to assess the patient-specific organ dose as a function of time in a typ-

ORIGINAL RESEARCH ■ MEDICAL PHYSICS

Figure 4

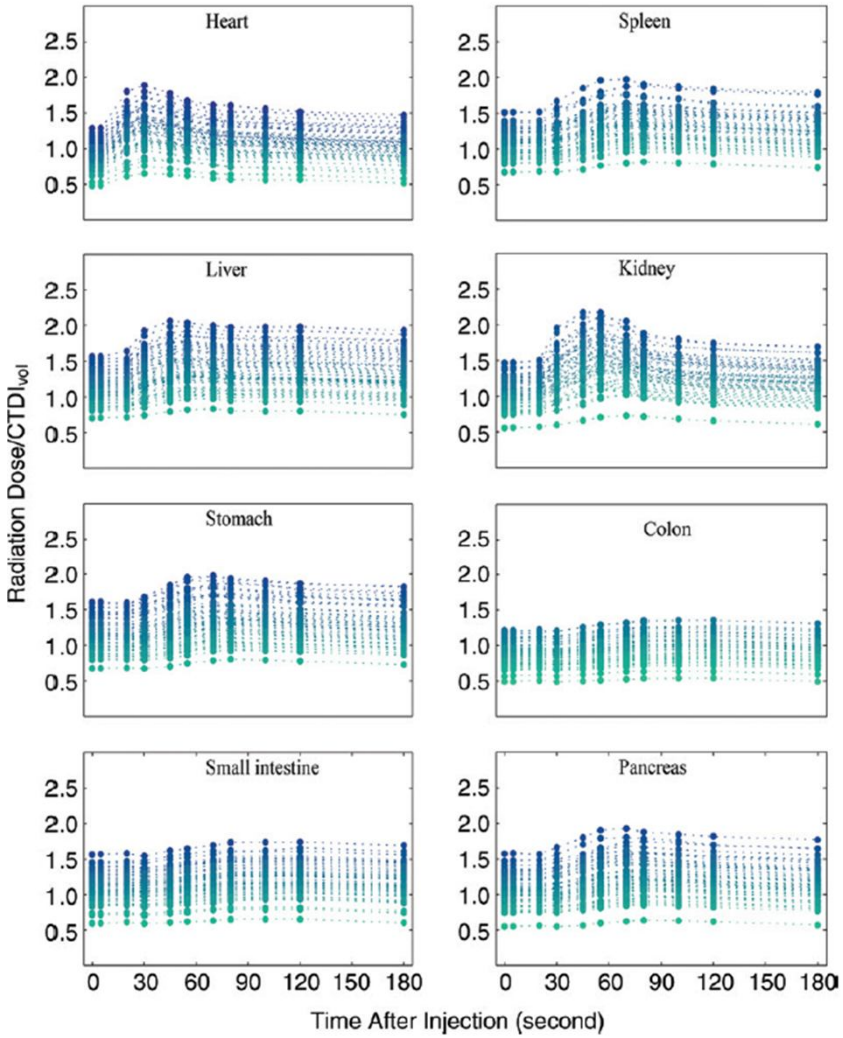


Figure 4: Graphs show results of Monte Carlo simulation of the organ dose to the heart, spleen, liver, kidneys, stomach, colon, small intestine, and pancreas as a function of time across the XCAT models for a contrast-enhanced abdominal CT examination. The organ doses are normalized by $CTDI_{vol}$.

Implication for Patient Care

- Contrast enhancement is used in more than 60% of CT imaging studies, which not only remarkably affects the CT image quality but also increases the total radiation dose.

The effect of iodine uptake on radiation dose absorbed by patient tissues in contrast enhanced CT imaging: Implications for CT dosimetry

Abstract

Objectives To investigate the effect of iodine uptake on tissue/organ absorbed doses from CT exposure and its implications in CT dosimetry.

Methods The contrast-induced CT number increase of several radiosensitive tissues was retrospectively determined in 120 CT examinations involving both non-enhanced and contrast-enhanced CT imaging. CT images of a phantom containing aqueous solutions of varying iodine concentration were obtained. Plots of the CT number increase against iodine concentration were produced. The clinically occurring iodine tissue uptake was quantified by attributing recorded CT number increase to a certain concentration of aqueous iodine solution. Clinically occurring iodine uptake was represented in mathematical anthropomorphic phantoms. Standard 120 kV CT exposures were simulated using Monte Carlo methods and was 0.82% w/w. For the same CT exposure, iodinated tissues were found to receive higher radiation dose than non-iodinated tissues, with dose increase exceeding 100% for tissues with high iodine uptake.

Conclusions Administration of iodinated contrast medium considerably increases radiation dose to tissues from CT exposure.

Key-points

- *Radiation absorption ability of organs/tissues is considerably affected by iodine uptake*
- *Iodinated organ/tissues may absorb up to 100 % higher radiation dose*
- *Compared to non-enhanced, contrast-enhanced CT may deliver higher dose to patient tissues*
- *CT dosimetry of contrast-enhanced CT imaging should encounter tissue iodine uptake*

ARTICLE INFO

Keywords:
Thyroid
Pediatric
Iodinated contrast agent
CT
Radiation dose

Highlights

- The thyroid radiation dose from contrast-enhanced CT may be highly underestimated.
- The effect of iodinated contrast uptake should be encountered in thyroid dosimetry.
- The thyroid is frequently included in imaged volume of pediatric chest CT exams.
- Meticulous demarcation of imaged volume in pediatric chest CT exams is imperative.

Cancer screening of asymptomatic individuals using 18F-FDG PET/CT in China: a retrospective study.

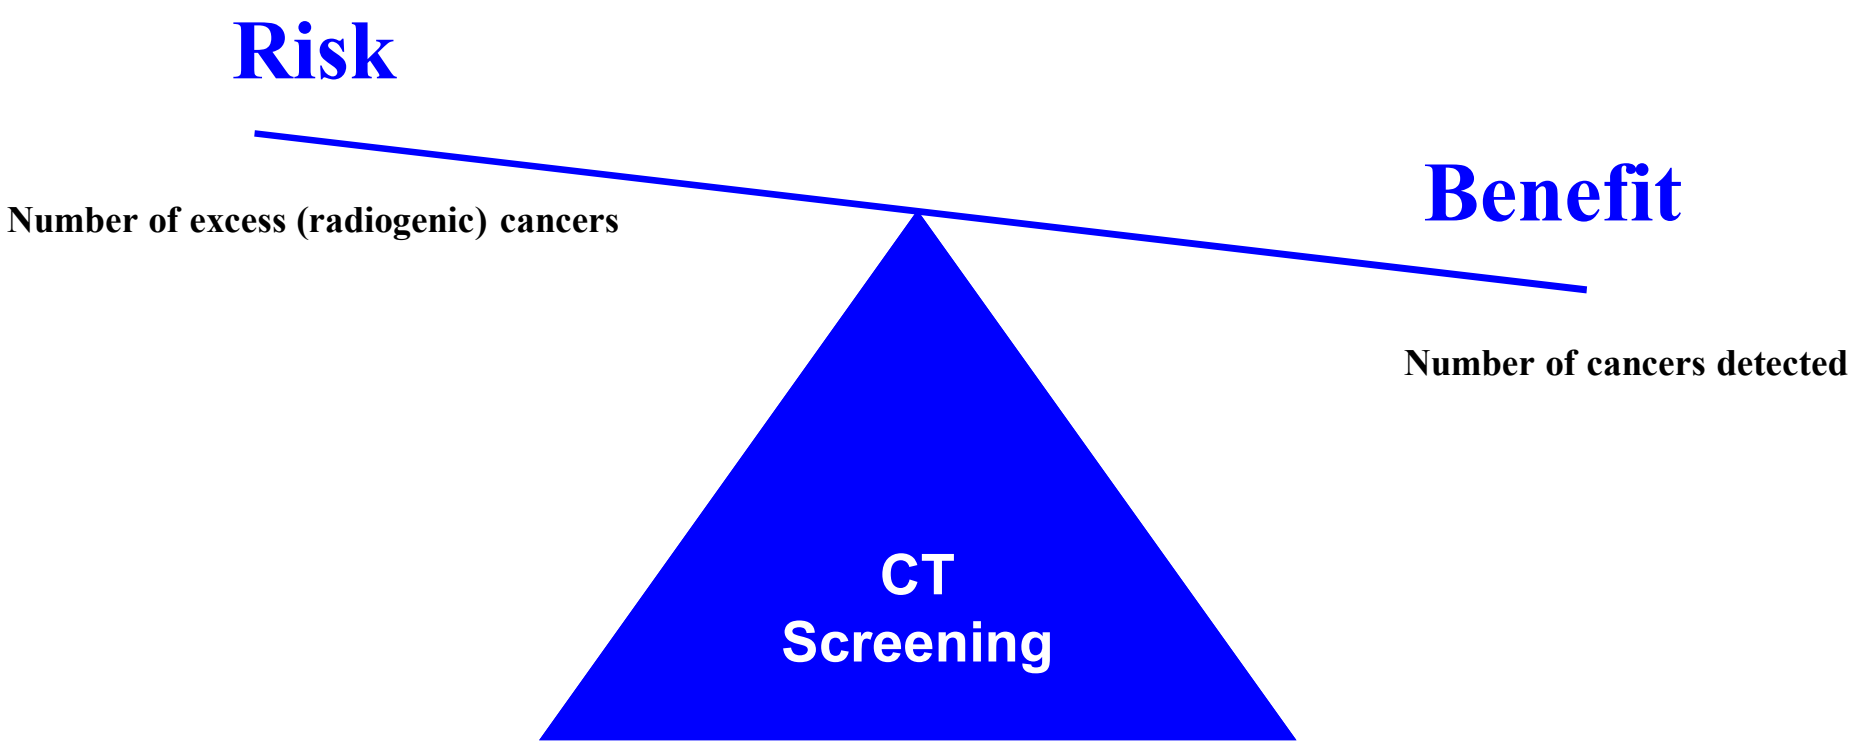
Tong J[1,2], Zou Y[3,2], Jiang J[4], Shi W[4], Tao R[4], Ye J[4], Lu Y[4], Jiang X[5,2], Wang W[6,2].

Author information

Abstract

BACKGROUND: In recent years, the application of 18F-fluorodeoxyglucose (FDG) positron emission tomography (PET)/computed tomography (CT) for voluntary cancer screening of asymptomatic individuals is becoming more and more popular in China. However, the utility of such screening is still controversial.

Benefits vs. risks

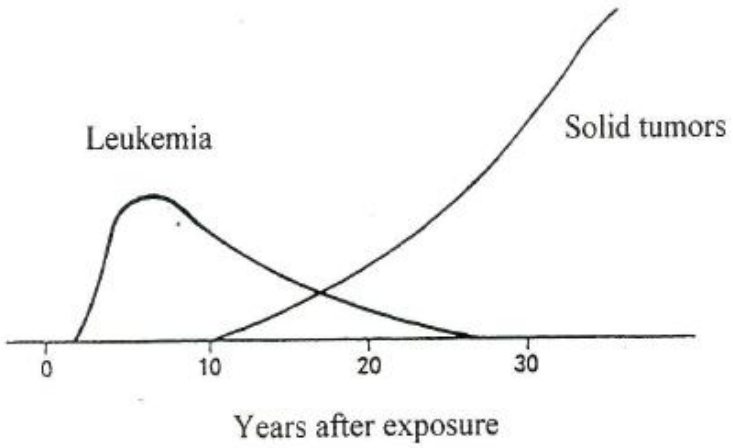


How do we estimate risk of radiation-induced cancer following CT for screening?

Epidemiological studies

It is not feasible to study the risk of radiogenic cancer from screening CT scans directly

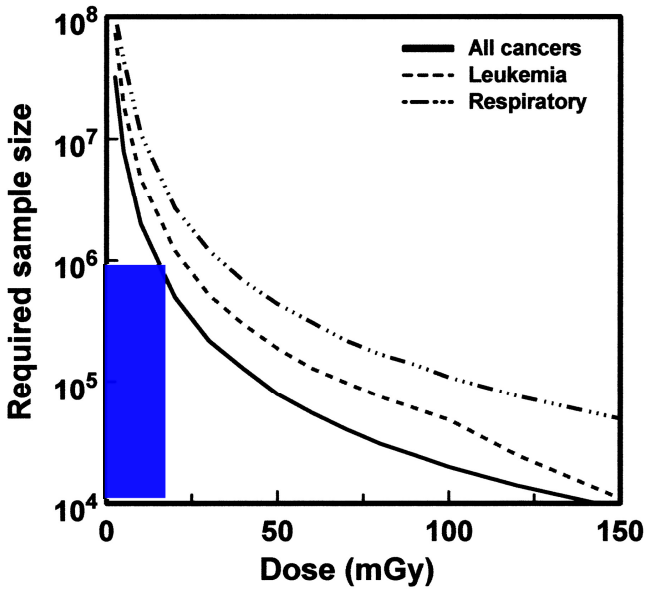
- **very long term patient follow-up due to the long latency for cancer development after exposure**



Epidemiological studies

It is not feasible to study the risk of radiogenic cancer from screening CT scans directly

- **very large number of patients needed to perform statistical analysis**



Size of a cohort which would be required to detect a significant increase in cancer mortality in that cohort, assuming lifetime follow-up.

Brenner et al, PNAS 100:13761-13766, 2003

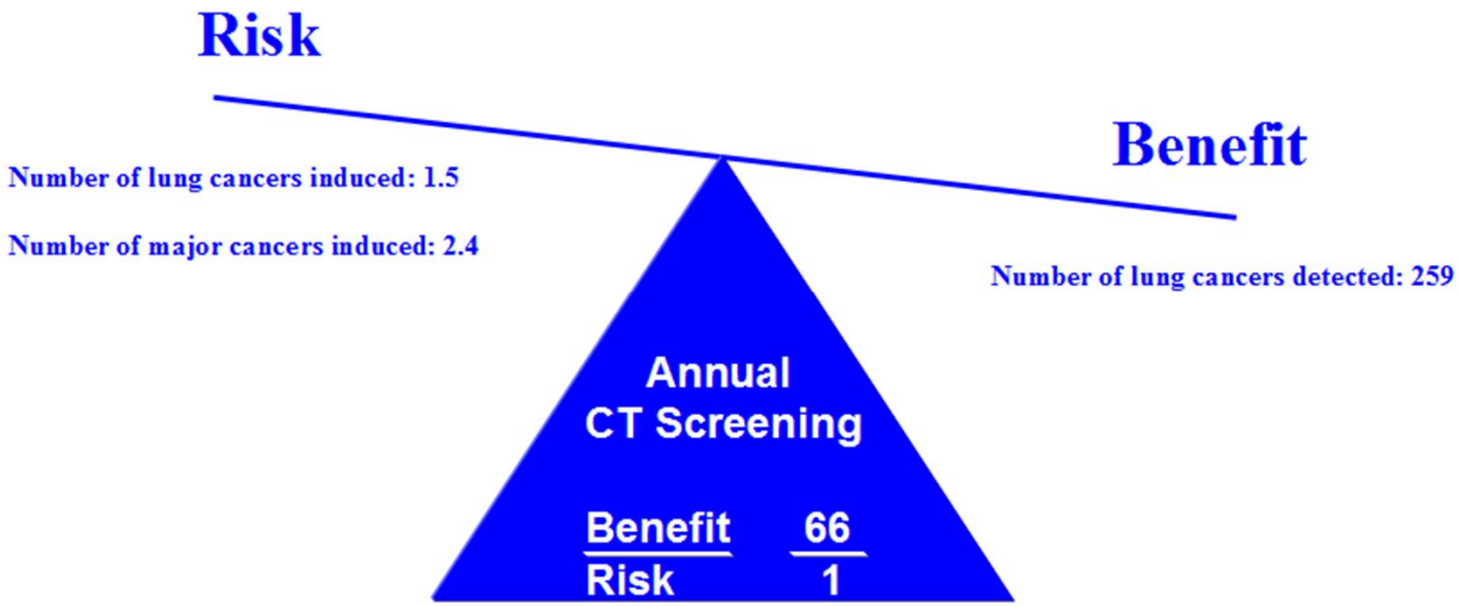
Table 3 | Number of lung cancers detected after 10 years of CT screening and number of estimated lung and major cancers associated with radiation exposure, according to age and sex of COSMOS trial participants

Participant age and sex at start of screening	No of participants	No of lung cancers detected	No of estimated radiation induced lung cancers (LAR/10 000)	No of estimated radiation induced major cancers* (LAR/10 000)
50-54				
Male	1153	35 (1 in 33)	0.24 (2.1)	0.43 (3.7)
Female	606	19 (1 in 32)	0.33 (5.5)	0.49 (8.1)
55-59				
Male	1114	56 (1 in 20)	0.21 (1.9)	0.38 (3.4)
Female	611	31 (1 in 20)	0.31 (5.1)	0.44 (7.2)
60-64				
Male	716	54 (1 in 13)	0.12 (1.7)	0.22 (3.0)
Female	345	13 (1 in 27)	0.16 (4.5)	0.21 (6.2)
≥65				
Male	456	41 (1 in 11)	0.07 (1.4)	0.12 (2.6)
Female	202	10 (1 in 20)	0.08 (3.8)	0.10 (5.1)
All ages, both sexes	5203	259 detected	1.5 induced	2.4 induced

LAR=lifetime attributable risk.
*Cumulative LAR for cancers of the stomach, colon, liver, lung, bladder, thyroid, breast, ovaries, uterus, or leukaemia.

Benefit vs. Radiogenic risk



MEDIRAD project

Subtask 2.1.3 Development of an innovative software tool on image quality and radiation dose (UoC, *OvGU, IPC, VGR, UPDescartes, ISGlobal)* ***M12-M48***

Data produced in ST2.1.1 and ST2.1.2 will be integrated into a freeware modular software expert system [CT Image Quality and Radiation Dose (CT-IQURAD)] that will provide a) image quality information, b) accurate estimation of patient organ doses and c) estimation of radiogenic risk associated with chest CT examinations performed for several clinical indications. This tool will be of paramount importance for the determination of the optimal chest CT protocol based on the relation between clinical indication, required image quality and lowest achievable dose. The prototype will be clinically evaluated in the university hospitals participating in ST2.1.1. The 'organ dose and risk estimation' module can be stand alone or Windows based. This tool will be available by the end of the project for chest CT optimisation. For optimisation of CT examinations on other anatomical areas, further research would be needed using the same methodology.
