# An exciting time for Nuclear Medicine…

## Diagnostic Imaging

- Great advances in peptide radiochemistry with radiometals (e.g., $^{68}$Ga, $^{64}$Cu, $^{89}$Zr) for PET
- New devices: PET/MRI, solid state detectors, SiPMTs

## Therapeutics

- Great advances in peptide radiochemistry with radiometals (e.g., $^{177}$Lu, $^{67}$Cu, $^{90}$Y) for therapy
- New therapies: Metastatic NETs, Metastatic Prostate Ca, Metastatic Pancreatic AdenoCa

# Reported AEs for Diagnostic Radiopharmaceuticals

BRIEF COMMUNICATION

## Evaluation of Radiopharmaceutical Adverse Reaction Reports to the British Nuclear Medicine Society from 2007 to 2016

Tracia-Gay Kennedy-Dixon[1], Maxine Gossell-Williams[2], Margaret Cooper[1], Moez Trabelsi[1], and Sobhan Vinjamuri[3]

*[1]Radiopharmacy, Royal Liverpool and Broadgreen University Hospitals Trust, Liverpool, United Kingdom; [2]Pharmacology Section, Department of Basic Medical Sciences, University of the West Indies, Mona Campus, Kingston, Jamaica; and [3]Royal Liverpool and Broadgreen University Hospitals Trust (consultant), Liverpool, United Kingdom*

**Results:** During the study period, there were 204 reports of radiopharmaceutical adverse reactions, of which 13 were considered invalid, primarily because of incomplete entries or because a causal relationship between the radiopharmaceutical and the adverse reaction could not be determined. Tetrofosmin (34 reports) and oxidronate (32 reports) had the highest prevalence, followed by medronate (21 reports) and then sestamibi and nanocolloid (14 reports each). Rash (84 reports), itching (46 reports), and vomiting (30 reports) were the 3 most frequently occurring adverse reactions. Most reports (96.8%) were for diagnostic radiopharmaceuticals. **Conclusion:** The prevalence of adverse reactions to radiopharmaceuticals reported in the BNMS database remains low, with a frequency of 3.1 reports per 100,000 administrations in 2013 and 2.5 per 100,000 administrations in 2015. In our review spanning 10 years, we did not find any particular concern about the use of radiopharmaceuticals.

**Key Words:** radiopharmaceuticals; adverse reactions; BNMS; pharmacovigilance

**J Nucl Med 2017; 58:2010–2012**
DOI: 10.2967/jnumed.117.194092

**Summary ($D_x$ Radiopharmaceuticals):**

- 2.5 - 3.1 reports per 100,000 (0.0025% - 0.0031%)
- Most common symptoms: rash, itching, vomiting

**Comparison*:**

- Iodinated contrast: 1-12%
- Non-iodinated contrast: 3%

* Katayama H et al. Adverse reactions to ionic and nonionic contrast media. A report from the Japanese Committee on the Safety of Contrast Media. *Radiology*. 1990;175(3):621-628

# DIAGNOSTIC RADIOPHARMACEUTICALS – Adverse Reactions

- In the published literature concerning safety of PET drugs, in 1996 Silberstein, Ryan and the Pharmacopeia Committee of the Society of Nuclear Medicine published in the *Journal of Nuclear Medicine* reporting a five year prospective study of 18 collaborating institutions using a questionnaire which enumerated monthly the number of procedures used and the adverse reactions noted for radiopharmaceuticals and non-radioactive drugs used in nuclear medicine[†];

- The study utilized operational definitions for adverse reactions and significant adverse reactions and devised an algorithm to categorize probability of causation. The published study included a copy of the actual questionnaire, which required itemization of any and all radiopharmaceuticals administered, adverse reactions to radiopharmaceuticals, dose, route, reaction, *etc.*, as well as total non-radiopharmaceuticals (such as adenosine or dipyridamole) administered and adverse reactions to these agents;

- No reactions are reported for FDG PET. The study also performed a reference check of listed adverse reactions by references and no adverse reactions were listed by the U.S. Pharmacopeial Convention's Drug Information for the Health Care Professional, 1995;

- Silberstein and the Pharmacopeia Committee of the Society of Nuclear Medicine also conducted a retrospective and prospective study of the prevalence of adverse reactions to PET radiopharmaceuticals published in 1998 in the *Journal of Nuclear Medicine*[‡]. Dr. Silberstein reported 22 PET centres provided monthly adverse reaction data from 1994 to 1997 related to PET drug administration in 47,876 dosages. In addition, retrospective data was collected from the opening of these centres on 33,925 radiopharmaceutical dosages;

- **In no case were there any adverse reactions.**

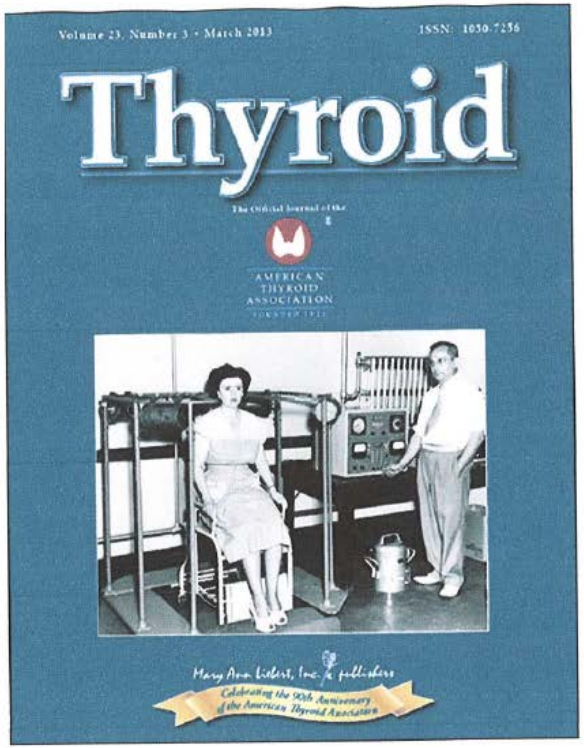
## Hertz to Use Nuclear Fission in Cure for Cancer

By Donald G. Vincent

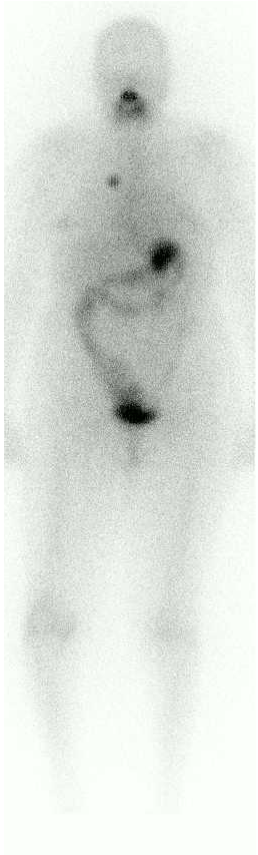
Dr. Saul Hertz, instructor in Medicine in the Medical School, has announced that he has founded an institution, The Radioactive Isotope Research Institute, whose purpose is to apply radioactive fission products to the treatment of the thyroid cancer, goiter, and other malignant growths.

Dr. Hertz is connected with both the Medical School and Beth Israel Hospital as medical associate and research associate. In the past, he has been in charge of the Thyroid Clinic of the Massachusetts General Hospital and Research Associate at the Massachusetts Institute of Technology.

The research conducted by Dr. Hertz and others which led to the Radioactive Isotope Research Institute, was financed by a grant from the John and Mary Markle Fund in New York City and the Milton N. Proctor Fund here. Most of the work was done at the Massachusetts General Hospital and at M.I.T.



# ADVERSE EVENTS – RADIOIODINE $^{131}$I (THYROID CANCER)



| Adverse Event | Reported Incidence | Transient/Chronic |
|---|---|---|
| Gastritis/Nausea | 30% | Transient |
| Radiation thyroiditis | 10%-20% | Transient |
| Sialadenitis | ≤ 30% | Transient |
| Xerostomia | 4%-20% | Chronic |
| Bone marrow suppression | 20% | Transient |
| Amenorrhea | 20%-27% | Transient |
| Dry eye | Rare | Transient |
| Leukaemia (Cum. Doses > 20 GBq) | Slight | Chronic |
| Second Primary Malignancy | No significant risk | - |

Data are n (%). Table shows grade 3 or worse haematological events occurring in at least 5% of patients, grade 3 or worse non-haematological events occurring in at least 5% of patients, and all SIRT-associated adverse events. Worst grade reported per patient per category, sorted by prevalence of grade 3 or worse. SIRT=selective internal radiotherapy.

***Table 2*: Adverse events reported in each treatment group**

# Extravasated Injection – [$^{177}$Lu]Lutate Therapy

# CONCLUSIONS

Diagnostic radiopharmaceuticals are extremely safe:

- Homeopathic amount of active compound involved
- Low levels of exposure to ionising radiation
- Addition of CT to SPECT & PET has roughly doubled the radiation dose

Radionuclide therapies are well tolerated in most subjects:

- Low levels of active compound
- Most reported AEs are usually transient
- Bone marrow is usually considered the organ at risk
- Very low levels of long-term or late effects such as secondary malignancy
