

Optimization of CT Simulation Imaging

Ingrid Reiser

Dept. of Radiology

The University of Chicago

Optimization of CT imaging

Goal: Achieve image quality that allows to perform the task at hand (diagnostic task), at the lowest possible dose

- Amount of image noise that is tolerable depends on procedure that is being performed

Example: Placement of a brachytherapy applicator

- Current workflow:
 - Many images are being acquired during applicator placement
- Dose reduction strategies:
 - Use low mAs for repeat imaging during procedure, where noise can be tolerated
 - Restrict the scan region to volume-of-interest
- Good overall image quality in final image only

Keeping track of CT Dose: CTDI_{vol}

- CTDI_{vol} : Computed tomography dose index
 - Represents the dose to a 14.5 cm tall PMMA cylinder during a CT scan
 - Includes dose from scatter tails in MDCT
 - CTDI_{vol} varies with mAs, kVp and accounts for helical pitch
 - 32cm diameter phantom for body protocols
 - 16cm diameter phantom for head/pediatric protocols

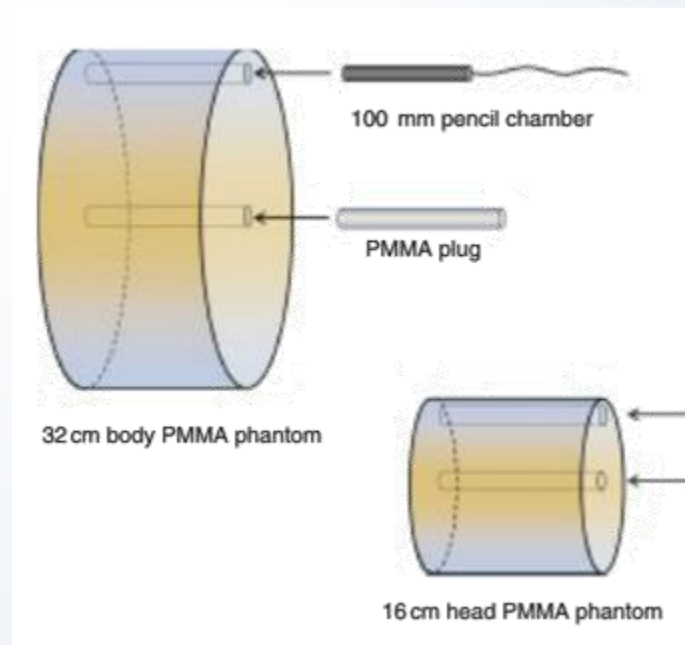

CT dose measurement

A 100mm pencil ion chamber is used to measure the integrated dose profile $D(z)$ along the scanner axis :

$$CTDI_{100} = \frac{1}{nT} \int_{L=-50mm}^{+50mm} D(z)dz$$

The dose to the phantom, $CTDI_w$, is estimated by weighting $CTDI_{100}$ in the center and periphery of the phantom:

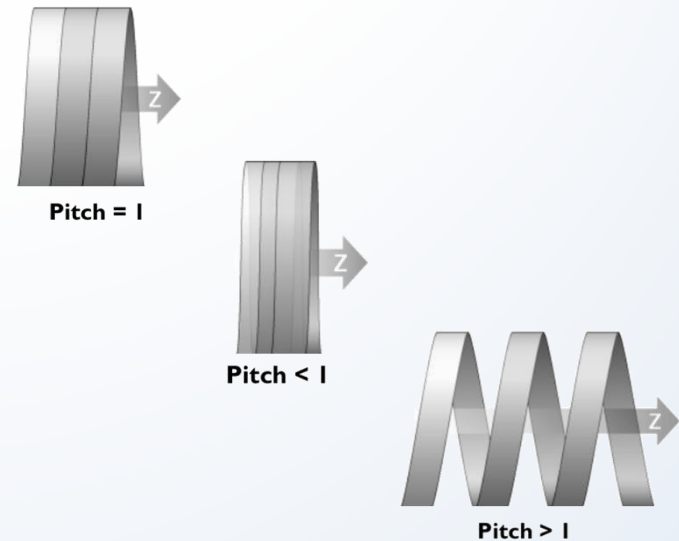

$$CTDI_w = \frac{1}{3}CTDI_{100,center} + \frac{2}{3}CTDI_{100,periph}$$

Bushberg, 2012

CT dose index: $CTDI_{vol}$

- In a helical scan, the table is translated while the gantry rotates
 - pitch = 1: Table increment/rotation equal to x-ray beam width
 - pitch < 1: Overlapping scans
 - pitch > 1: Gaps in scan (artifacts)
- $CTDI_{vol}$ is the volume-weighted dose index that accounts for pitch:

$$CTDI_{vol} = \frac{CTDI_w}{pitch}$$

Where to find guidance

- Use diagnostic CT as a guideline:
 - The AAPM has published CT protocols
<http://www.aapm.org/pubs/CTProtocols/>
- Diagnostic reference levels (DRL):
 - 75th percentile of CTDI_{vol} of all examinations
 - Achievable dose (AD) – 50th percentile
 - Based on multi-institution, nationwide data

DRL for CTDI_{vol}

Table 3
Diagnostic Reference Levels and Achievable Doses for Adult and Pediatric CT (CTDI_{vol})

| | Patient Lateral (LAT) Dimension | CTDI Phantom Diameter (cm) | DRL (mGy) | AD (mGy) |
|---|--|---------------------------------------|------------------|-----------------|
| Adult head [6,9] | 16 | 16 | 75 | 57 |
| Adult abdomen-pelvis [6,9] | 38 | 32 | 25 | 17 |
| Adult Chest [6] | 35 | 32 | 21 | 14 |
| Pediatric 5 year old head [6] | 15 | 16 | 40 | 31 |
| Pediatric 5 year old abdomen-pelvis [9] | 20 | 16 | 20 | 14 |

ACR–AAPM practice parameter for diagnostic reference levels and achievable doses in medical x-ray imaging (2014)

Dose-length product

- $CTDI_{vol}$ by itself is independent of the scan volume
 - No information on dose to patient
- Dose-length product (DLP) incorporates scan length L:

$$DLP = L * CTDI_{vol}$$

Effective dose can be estimated from DLP:

Multisection CT protocols: Sex- and age-specific conversion factors to determine effective dose from dose-length product. P Deak, Y Smal, W Kalender. *Radiology*, 257 (2010)

I'm ready to scan my patient. How can I know $CTDI_{vol}$ and DLP?

- $CTDI_{vol}$ and DLP are displayed on the scanner console prior to performing a scan!

The screenshot shows a CT scanner console interface with various parameters and calculated dose values. The parameters are as follows:

| Parameter | Value | Unit |
|------------------|---|---------|
| Label | | |
| Start | * | |
| End | * | |
| Length | 250.2 | |
| Direction | <input type="radio"/> In <input checked="" type="radio"/> Out | |
| Thickness | 0.9 | mm |
| Increment | 0.45 | mm |
| DoseRight | <input checked="" type="checkbox"/> Z-DOM | |
| kV | 120 | |
| mAs/Slice | 250 | |
| Average mAs (mA) | 250 | (200) |
| Preview | <input checked="" type="checkbox"/> | |

At the bottom, a blue bar displays the calculated dose values:

| Images | CTDI | DLP |
|--------|---------|-------------|
| 555 | 15.3mGy | 469.0mGy*cm |

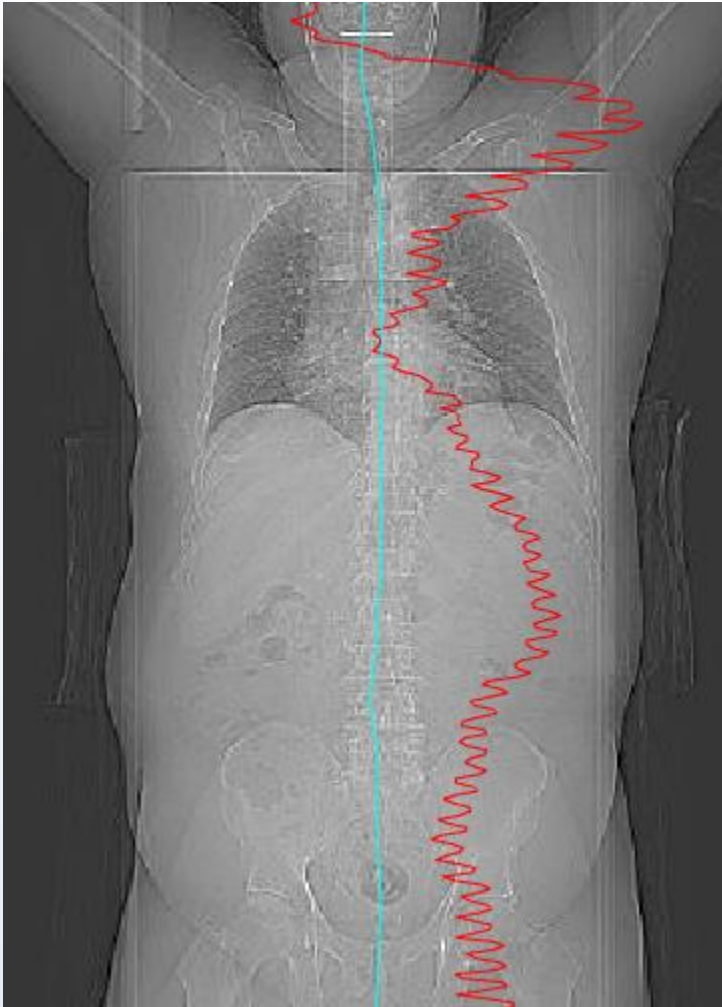

Below the blue bar, a yellow box indicates the Phantom size: 16cm.

The pre-scan CTDI_{vol} or DLP is high. What can I do to reduce it?

Adjusting these parameters can reduce CTDI_{vol} :

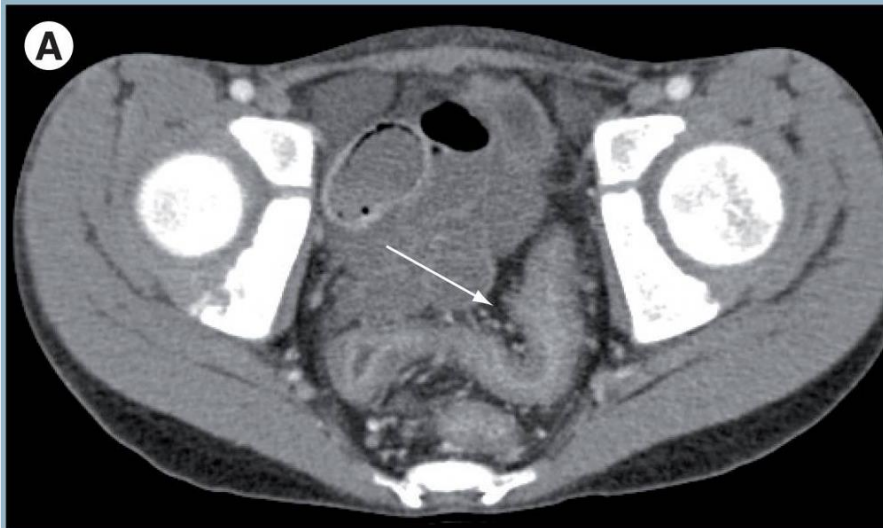

- mAs
- Pitch
- kVp
- X-ray beam collimation
 - Does not affect displayed CTDI_{vol} , but affects dose efficiency
- Tube current modulation
 - Does not directly affect displayed CTDI_{vol} , but will reduce dose in less attenuating anatomical regions, such as thorax

Tube current modulation

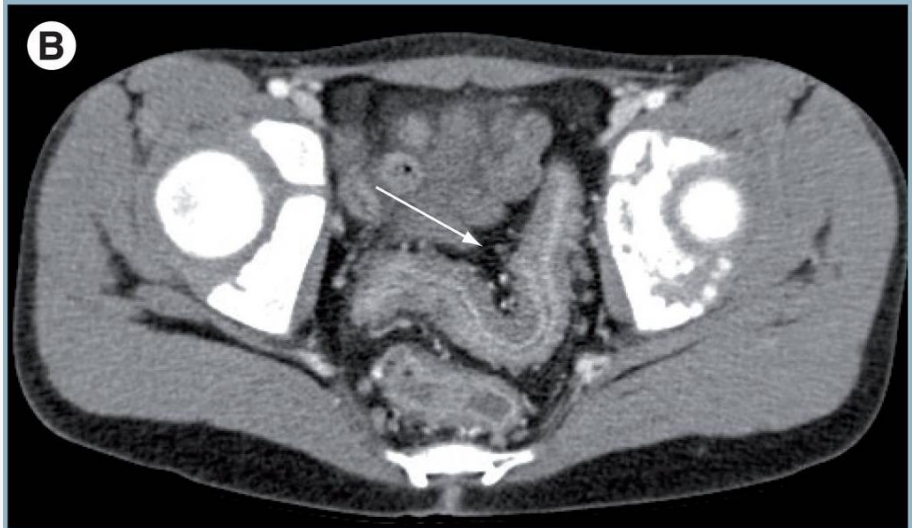

Tube mA varies to compensate for changes of attenuation in different anatomic regions

Effect of kVp on CTDI_{vol}

120 kV, $\text{CTDI}_{\text{vol}} = 5.18 \text{ mGy}$

100 kV, $\text{CTDI}_{\text{vol}} = 3.98 \text{ mGy}$

From: L. Yu et al, Radiation dose reduction in computed tomography: techniques and future perspective. Imaging Med. 2009 Oct; 1(1): 65–84.

| Parameter | Effect on Dose |
|-----------------|---|
| mAs | Reducing mAs reduces dose mAs proportional to $CTDI_{vol}$! |
| Pitch | Increasing pitch reduces dose |
| kVp | Lowering kVp will reduce $CTDI_{vol}$. Relationship is not linear. |
| Collimation | Use widest possible collimation |
| Scan range | Restrict the scan range to the region of interest. Reduces DLP, no effect on $CTDI_{vol}$. Particularly important for repeat scans. |
| Dose modulation | Aims to maintain same noise level In combination scans (Chest/Abd) |

Which statement is FALSE?

$CTDI_{vol}$ is ...

20% 1. proportional to mAs

20% 2. patient dose

20% 3. represents the scanner output

20% 4. inverse proportional to pitch

20% 5. based on a reference phantom

Correct Answer:

2: CTDI_{vol} is **NOT** patient dose

Reference:

- Cynthia H. McCollough, CT dose: how to measure, how to reduce. Health Physics **95**, (2008) 508–517.

My planning CT image does not show the same anatomic detail as the diagnostic CT. How can I improve it?

CT reconstruction parameters

There are many reconstruction parameters that strongly affect the CT image appearance. These parameters need to be chosen according to anatomic structures to be visualized.

There may be differences in how the scans are performed that will affect image quality, such as breath hold or free breathing, or administration of contrast agent.

Review: CT reconstruction parameters

- Reconstruction field-of-view/matrix size
 - In planning scans, the FOV is larger because it includes more anatomy such as elbows
 - The matrix size on a scanner tends to be fixed to 512x512, which can produce large pixel sizes to cover large area
 - To increase resolution, increase matrix size or decrease FOV
- Reconstruction filter
 - Standard B: CT # most accurate, high-resolution detail may be blurred
 - Y-Sharp: Better high-frequency detail
- Slice thickness, spacing
 - Thick slices are less noisy
 - Slice spacing as close as needed

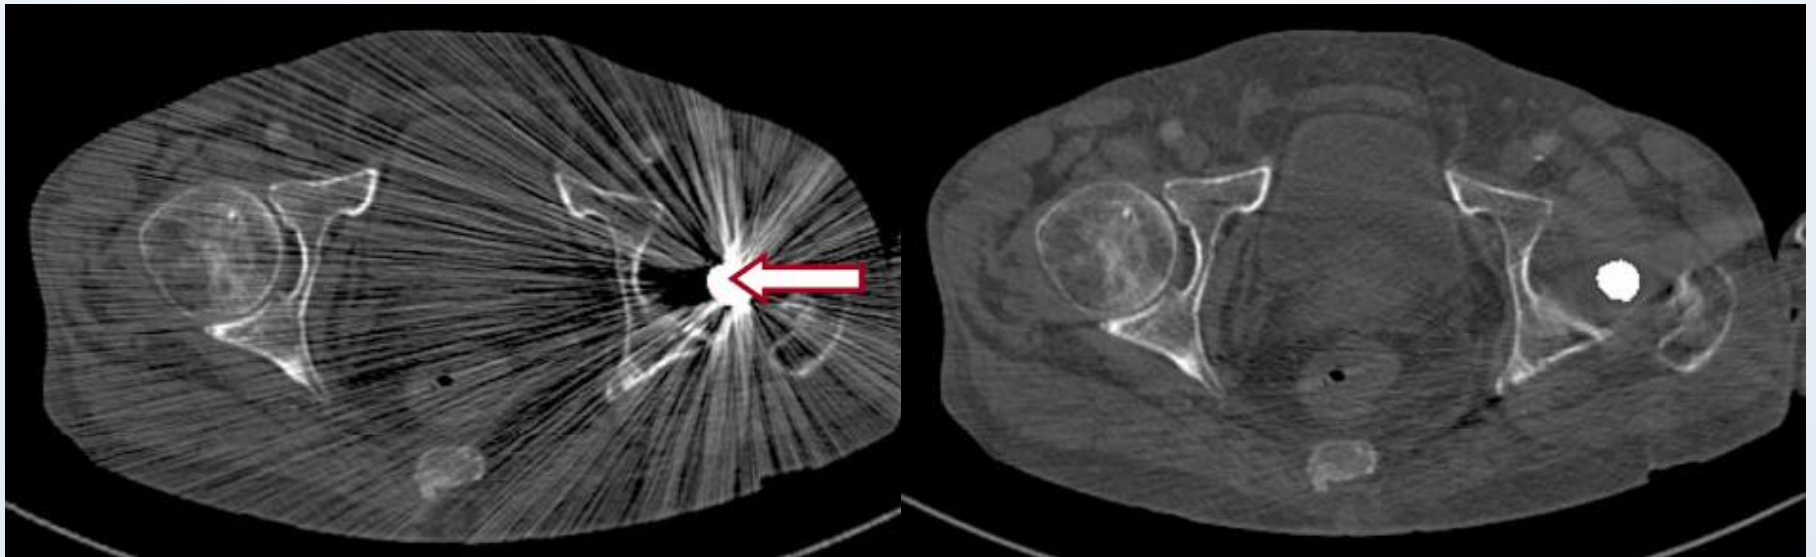

Review: CT reconstruction parameters

- Multiple reconstructions from one CT acquisition
 - Re-reconstruct with different parameter settings to improve anatomic detail
- Display window settings
 - Different window width/level settings portray different types of anatomy (lung window vs. soft-tissue or bone window)
- Iterative reconstruction (if available on system)
 - Can reduce noise in high-contrast object, such as lung tumors

Advanced image reconstruction tools: Metal artifact reduction (MAR)

Available on CT scanners as optional feature

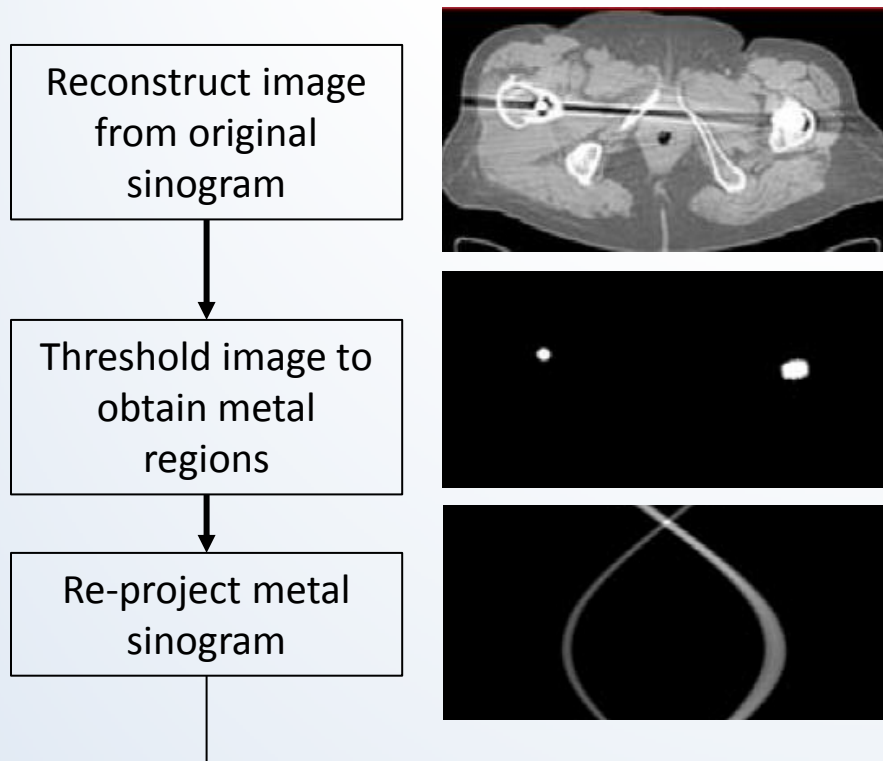

- Improvement of anatomic visibility
- Better CT # accuracy

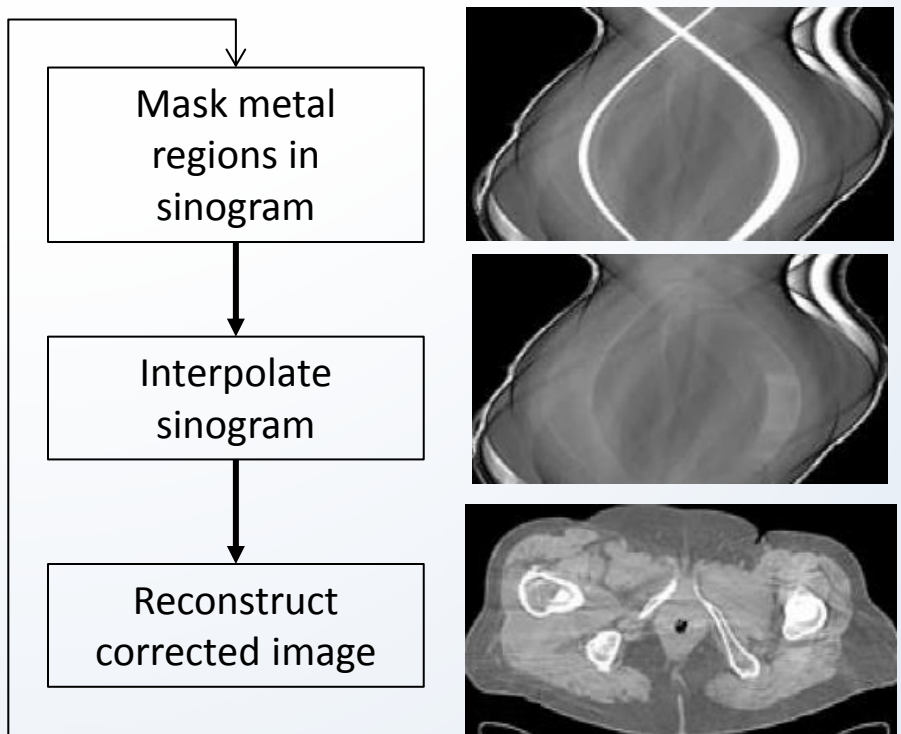

Meyer E et al., Normalized metal artifact reduction (NMAR) in computed tomography, Medical Physics, 37, 5482-5493 (2010)

General principle:

1. Identify metal regions

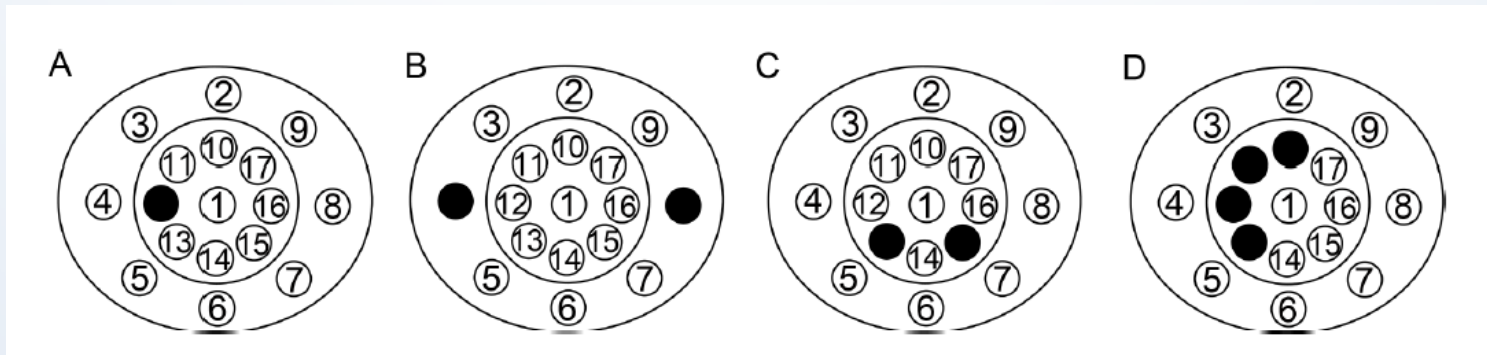

2. Correct sinogram

Evaluation of an iterative MAR-algorithm

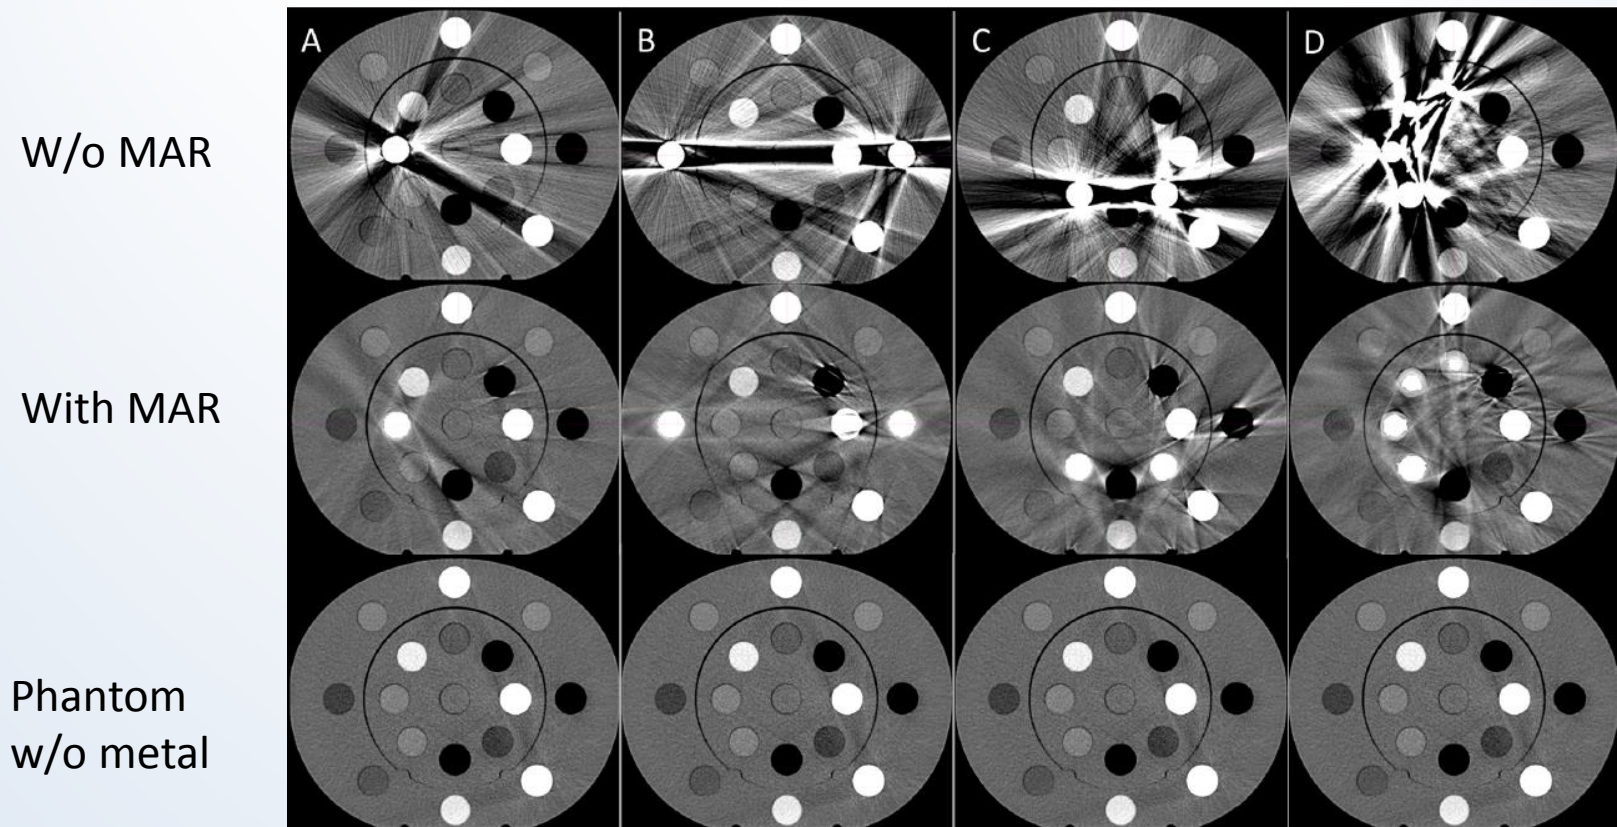

- The complexity of the metal structures affects the effectiveness of MAR.
- Use test phantom with different metal arrangements:

From: Axente M, et al., Clinical evaluation of the iterative metal artifact reduction algorithm for CT simulation in radiotherapy. Medical Physics, 42, 1170-1183 (2015)

CT number accuracy with MAR

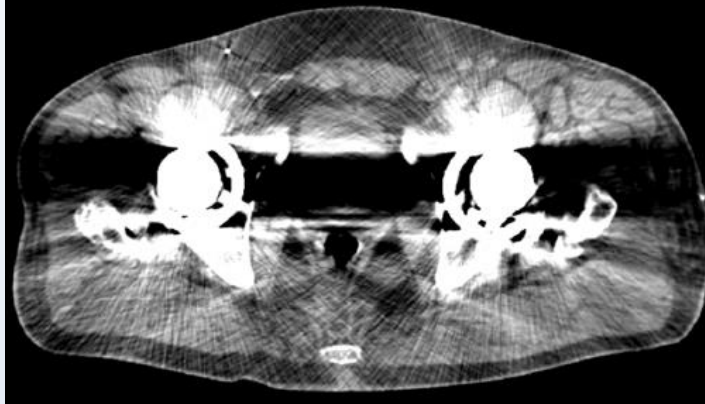

Evaluation of a prototype algorithm using a phantom with 25mm steel inserts:

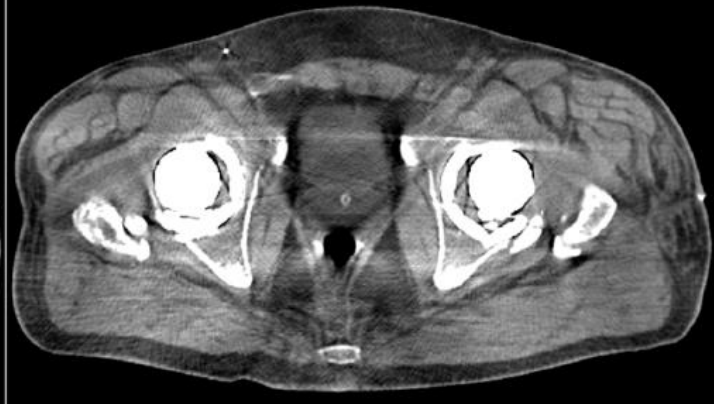

From: Axente M, et al., Clinical evaluation of the iterative metal artifact reduction algorithm for CT simulation in radiotherapy. Medical Physics, 42, 1170-1183 (2015)

Patient with hip implants

w/o MAR

with MAR

From: Axente M, et al., Clinical evaluation of the iterative metal artifact reduction algorithm for CT simulation in radiotherapy. Medical Physics, 42, 1170-1183 (2015)

In which situation is metal artifact reduction (MAR) expected to be the least effective?

- | | |
|-----|---|
| 20% | 1. CT with hip prosthesis |
| 20% | 2. CT # accuracy |
| 20% | 3. CT with LDR Fletcher-Suit applicator |
| 20% | 4. CT with spinal fixation rods |
| 20% | 5. CT with dental filling artifacts |

Correct Answer:

5: CT with dental filling artifacts.

Close arrangements of several metal objects is most difficult to correct for.

Pediatric patients

- Image gently: “child-size” radiation
 - Children are more sensitive to radiation and have a longer lifetime during which cancer may develop
 - Instructions for child-sizing CT protocols on image gently website

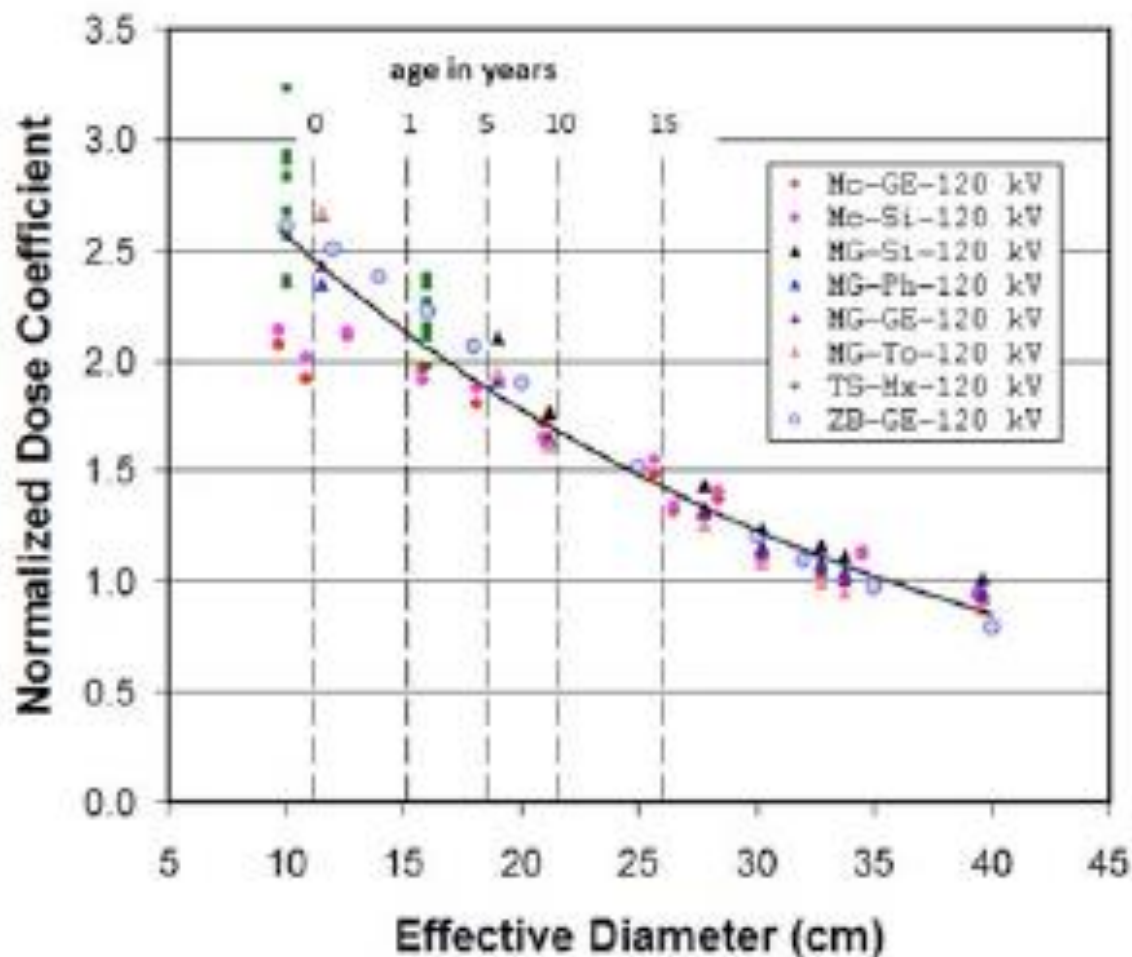

<http://www.imagegently.org/Portals/6/Procedures/IG%20CT%20Protocols%20111714.pdf>

Size-specific dose estimate (SSDE)

- SSDE is an estimate of the absorbed dose to a uniform phantom
- Dose conversion coefficients allow to infer size-specific doses for a given CTDIvol

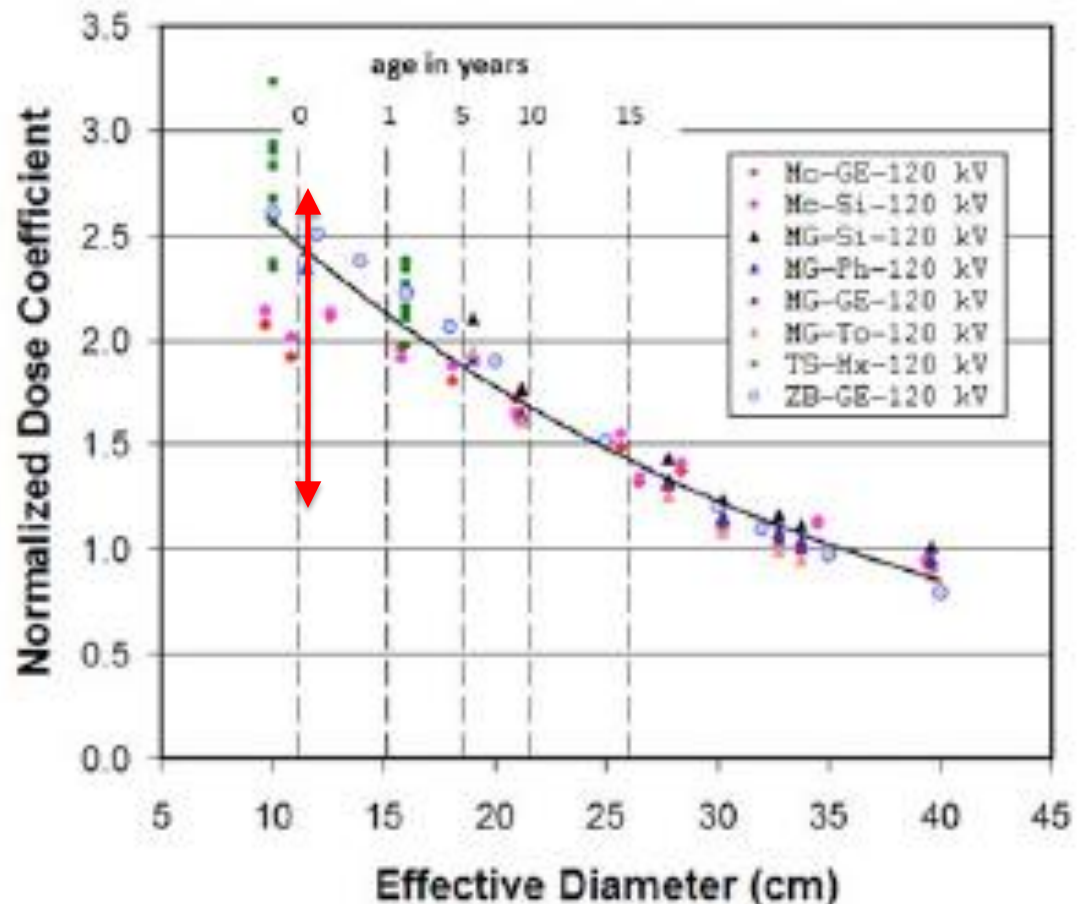

Normalized Dose Coefficients for the 32cm CTDI phantom

How to child-size protocols

For the same acquisition parameters, the dose to a newborn is much higher than that to an adult

-> Reduce mAs so as to match SSDE

How to child-size protocols

Image gently: Match SSDE for pediatric patients with that for adults

| Age | Effective Diameter (cm) | $f = \text{SSDE}/\text{CTDI}_{\text{vol}}$ conv. factor | mAs reduction factor $f_{\text{adult}}/f_{\text{child}}$ | SSDE (mGy) |
|---------|-------------------------|--|---|------------|
| newborn | 12 | 2.38 | 0.52 | 23 |
| 1yr | 14 | 2.22 | 0.55 | 23 |
| 5yr | 17 | 1.98 | 0.62 | 23 |
| 10yr | 20 | 1.53 | 0.7 | 23 |
| ADULT | 30 | 1.23 | 1 | 23 |

Child-sizing protocols

Image gently suggests more aggressive dose reduction for younger patients:

| Age | Effective Diameter (cm) | CTDI _{vol} to SSDE conversion factor | mAs reduction factor | | |
|---------|-------------------------|---|-------------------------|----------|------------|
| | | | Limited (matching SSDE) | Moderate | Aggressive |
| newborn | 12 | 2.38 | 0.52 | 0.39 | 0.25 |
| 1yr | 14 | 2.22 | 0.55 | 0.42 | 0.29 |
| 5yr | 17 | 1.98 | 0.62 | 0.50 | 0.39 |
| 10yr | 20 | 1.53 | 0.7 | 0.62 | 0.53 |
| ADULT | 30 | 1.23 | 1 | 1 | 1 |

Child-sizing protocols: example

Download CT protocols (excel) from image gently website,
[http://www.imagegently.org/Portals/6/IG%20CT%20PPT%20Tables%20Web%20Version%20\(12-16-14\).xls](http://www.imagegently.org/Portals/6/IG%20CT%20PPT%20Tables%20Web%20Version%20(12-16-14).xls)

weight (age)
specific mAs:

Worksheet is locked, only yellow fields can be modified.

For a given CTDIvol, how different is the SSDE in newborns compared to SSDE for adults?

20% 1. They are equal

20% 2. about 4x greater

20% 3. about 4x lower

20% 4. about 2x greater

20% 5. about 2x lower

Correct Answer:

4: about 2x greater.

The size-specific dose estimate for newborns is about twice that for an adult, for the same $CTDI_{vol}$.
